# Work in Progress!

# Aims

- Experiment with MIVOT markup in VOTable
  - Can I parse it?
  - Can I represent this information in the internal table data model used by STIL\*?
  - Can I round-trip it?
- Experiment with MANGO data model
  - Does it provide what I need for astrometry manipulation?
  - Can I extract that from the MIVOT serialization?
- Provide implementation feedback
  - *this talk*

\* STIL: Starlink Tables Infrastructure Library, the table I/O library underlying TOPCAT and STILTS

# Standards

As Laurent has already explained:

- **VO-DML** is a way of expressing data models in the VO  
[REC-VODML-1.0-20180910](#)
- **MIVOT** embeds any VO-DML-serialized data model into VOTable  
[REC-MIVOT-1.0-20230620](#)
- **MANGO** is a data model for encoding data about astronomical sources  
<https://github.com/lmichel/MANGO>

# Gaia Astrometry and Epoch Propagation

## Aim:

Propagate Gaia positions and errors to some future/past date

## Requirement:

5\* parameter astrometry including full covariance matrix ( $5 + 5 \times 5 = 30$  elements with some symmetry)

The `gaia_source` table supplies this information as:

- 5 astrometric parameters:

`ra, dec, parallax, pmra, pmdec`

- 5 errors:

`ra_err, dec_err, parallax_err, pmra_err, pmdec_err`

- 10 correlations:

`ra_dec_corr`      `ra_parallax_corr`      `ra_pmra_corr`      `ra_pmdec_corr`  
`dec_parallax_corr`      `dec_pmra_corr`      `dec_pmdec_corr`  
`parallax_pmra_corr`      `parallax_pmdec_corr`  
`pmra_pmdec_corr`

## Task:

- Encode this information in MIVOT using MANGO
- Decode it for use by TOPCAT

(\* or maybe 6 parameter, but let's ignore radial velocity here)

# MANGO Astrometry Encoding: Example

MIVOT-ised VOTable supplied by Laurent (VizieR [I/355/gaiadr3](#) marked up by hand)

- 5 parameters: easy!

# MANGO Astrometry Encoding: Comments

The encoding is complicated!

- Some specifics:
  - ▷ Some errors specified as diagonal elements of matrix with no off-diagonals
  - ▷ 5-parameter covariance matrix split up into (artificial from Gaia point of view) submatrices
  - ▷ Matrix element/specifications hard to remember
  - ▷ Some correlations appear multiple times, others don't
- Generally hard to get right
  - ▷ It took several iterations between Laurent and me to get version without (apparent?) errors
  - ▷ I can code a parser from the example document, but I don't think I could from MANGO text
  - ▷ I'm not confident my parser would work for a different VOTable with MANGO markup
  - ▷ If the encoding ends up looking like this, we need very robust validators! And people need to use them.

Maybe this complexity is justified

- Perhaps it enables encoding of non-Gaia-like astrometry

Or maybe not

- Do we currently have examples of astrometry tables requiring this flexibility?
- Or do we expect them in the foreseeable future?

# MANGO Astrometry Encoding: Alternative

A flat model would be much easier to work with:

```
<TEMPLATES>
<INSTANCE dmtype="mango:EpochPosition">
  <REFERENCE dmref="_spacesys_icrs" dmrole="mango:EpochPosition.coordSys" />
  <ATTRIBUTE dmrole="mango:EpochPosition.epoch" dmtype="coords:Epoch" value="2016.5" />
  <ATTRIBUTE dmrole="mango:EpochPosition.pmCosDeltApplied" dmtype="ivoa:boolean" value="true" />
  <ATTRIBUTE dmrole="mango:QuantityCorrelation.isCovariance" dmtype="ivoa:boolean" value="false" />

  <ATTRIBUTE dmrole="mango:EpochPosition.longitude" dmtype="ivoa:RealQuantity" ref="RA_ICRS" />
  <ATTRIBUTE dmrole="mango:EpochPosition.latitude" dmtype="ivoa:RealQuantity" ref="DE_ICRS" />

  <ATTRIBUTE dmrole="mango:EpochPosition.pmlonPmlatCor" dmtype="ivoa:RealQuantity" ref="pmlonPmlatCor" />
</INSTANCE>
</TEMPLATES>
```

Yes the details look a bit Gaia-specific

- But Gaia is the main(?) example for this, and will be for a while
- Would doing it like this cause problems for any important use cases?

# Parsed DM Manipulation

MIVOT describes structured objects per-table/per-row

- Data structure elements reference columns by column name/ID

This is not very suitable for TOPCAT to use in its internal table data model

- TOPCAT users can add/remove/rename/edit column metadata
- So a per-table structure referencing columns could become invalid after load
- (do similar considerations apply to TAP services constructing MIVOT??)

So TOPCAT reconstructs an inverted model of MIVOT DM at load time

- each column contains a description of its role(s) in the MIVOT structure
- This works (I think), but it's not very elegant

Round-tripping should be possible, but:

- It requires some effort
- I haven't tried it yet
- The round-tripped MIVOT markup might look cosmetically different from the input one

## Additional Requirements

- MIVOT example describes one `mango:EpochPosition` instance
- Sometimes multiple (named?) instances may be required
  - Following a join of two tables with epoch astrometry
  - Following propagation of epoch astrometry
- I suppose(?) MIVOT can cope with this (`COLLECTION?`)
- But it will add more complication to the client-side processing

# Implementation Progress

## Epoch astrometry propagation window

- Extracts astrometry columns from input table using MIVOT/MANGO markup
- Uses them as defaults to populate fields in astrometry propagation query window
- Adds new columns as instructed calculating propagated astrometry

## Status

- Missing features, not robust, various bugs
- But looks OK as proof of concept

The screenshot shows a software window titled "Astrometry Transformation". It is divided into two main sections: "Input" and "Output".

**Input Section:** This section contains a list of parameters, each with a dropdown menu for the value and another dropdown for the unit. The parameters are:

- epoch: 2016.5 (yr)
- lon: RA\_ICRS (deg)
- lat: DE\_ICRS (deg)
- parallax: Plx (mas)
- pmlon: pmRA (mas/yr)
- pmlat: pmDE (mas/yr)
- rv: RV (km/s)
- lonErr: e\_RA\_ICRS (mas)
- latErr: e\_DE\_ICRS (mas)
- parallaxErr: e\_Plx (mas)
- pmlonErr: e\_pmRA (mas/yr)
- pmlatErr: e\_pmDE (mas/yr)
- rvErr: e\_RV (km/s)
- lonLatCorr: RADEcor
- lonParallaxCorr: RAPlxcor
- lonPmlonCorr: RApmRAcor
- lonPmlatCorr: RApmDEcor
- latParallaxCorr: DEPlxcor
- latPmlonCorr: DEpmRAcor
- latPmlatCorr: DEpmDEcor
- parallaxPmlonCorr: PlxpmRAcor
- parallaxPmlatCorr: PlxpmDEcor
- pmlonPmlatCorr: pmRApmDEcor

**Output Section:** This section contains three fields:

- Epoch: 2024.5
- Conversions: Covariances
- Suffix: 2024

At the bottom of the window, there are "OK" and "Cancel" buttons. A right-pointing arrow is visible between the input and output sections.

## Conclusions

- MIVOT markup in VOTable is not too hard to parse
- MANGO can represent astrometry (e.g. Gaia 5/6-parameter fits with or without covariances)
  - but the representation is (unnecessarily?) complicated
  - I suggest flattening and simplifying it
- Representing MIVOT data in a TOPCAT table can be done
  - the implementation code is not very pretty
  - but that's probably unavoidable given what it's trying to do
- Multiple MANGO astrometry instances per table may be necessary
