

# How does SimDM handle data provenance ?

**Provenance Day**

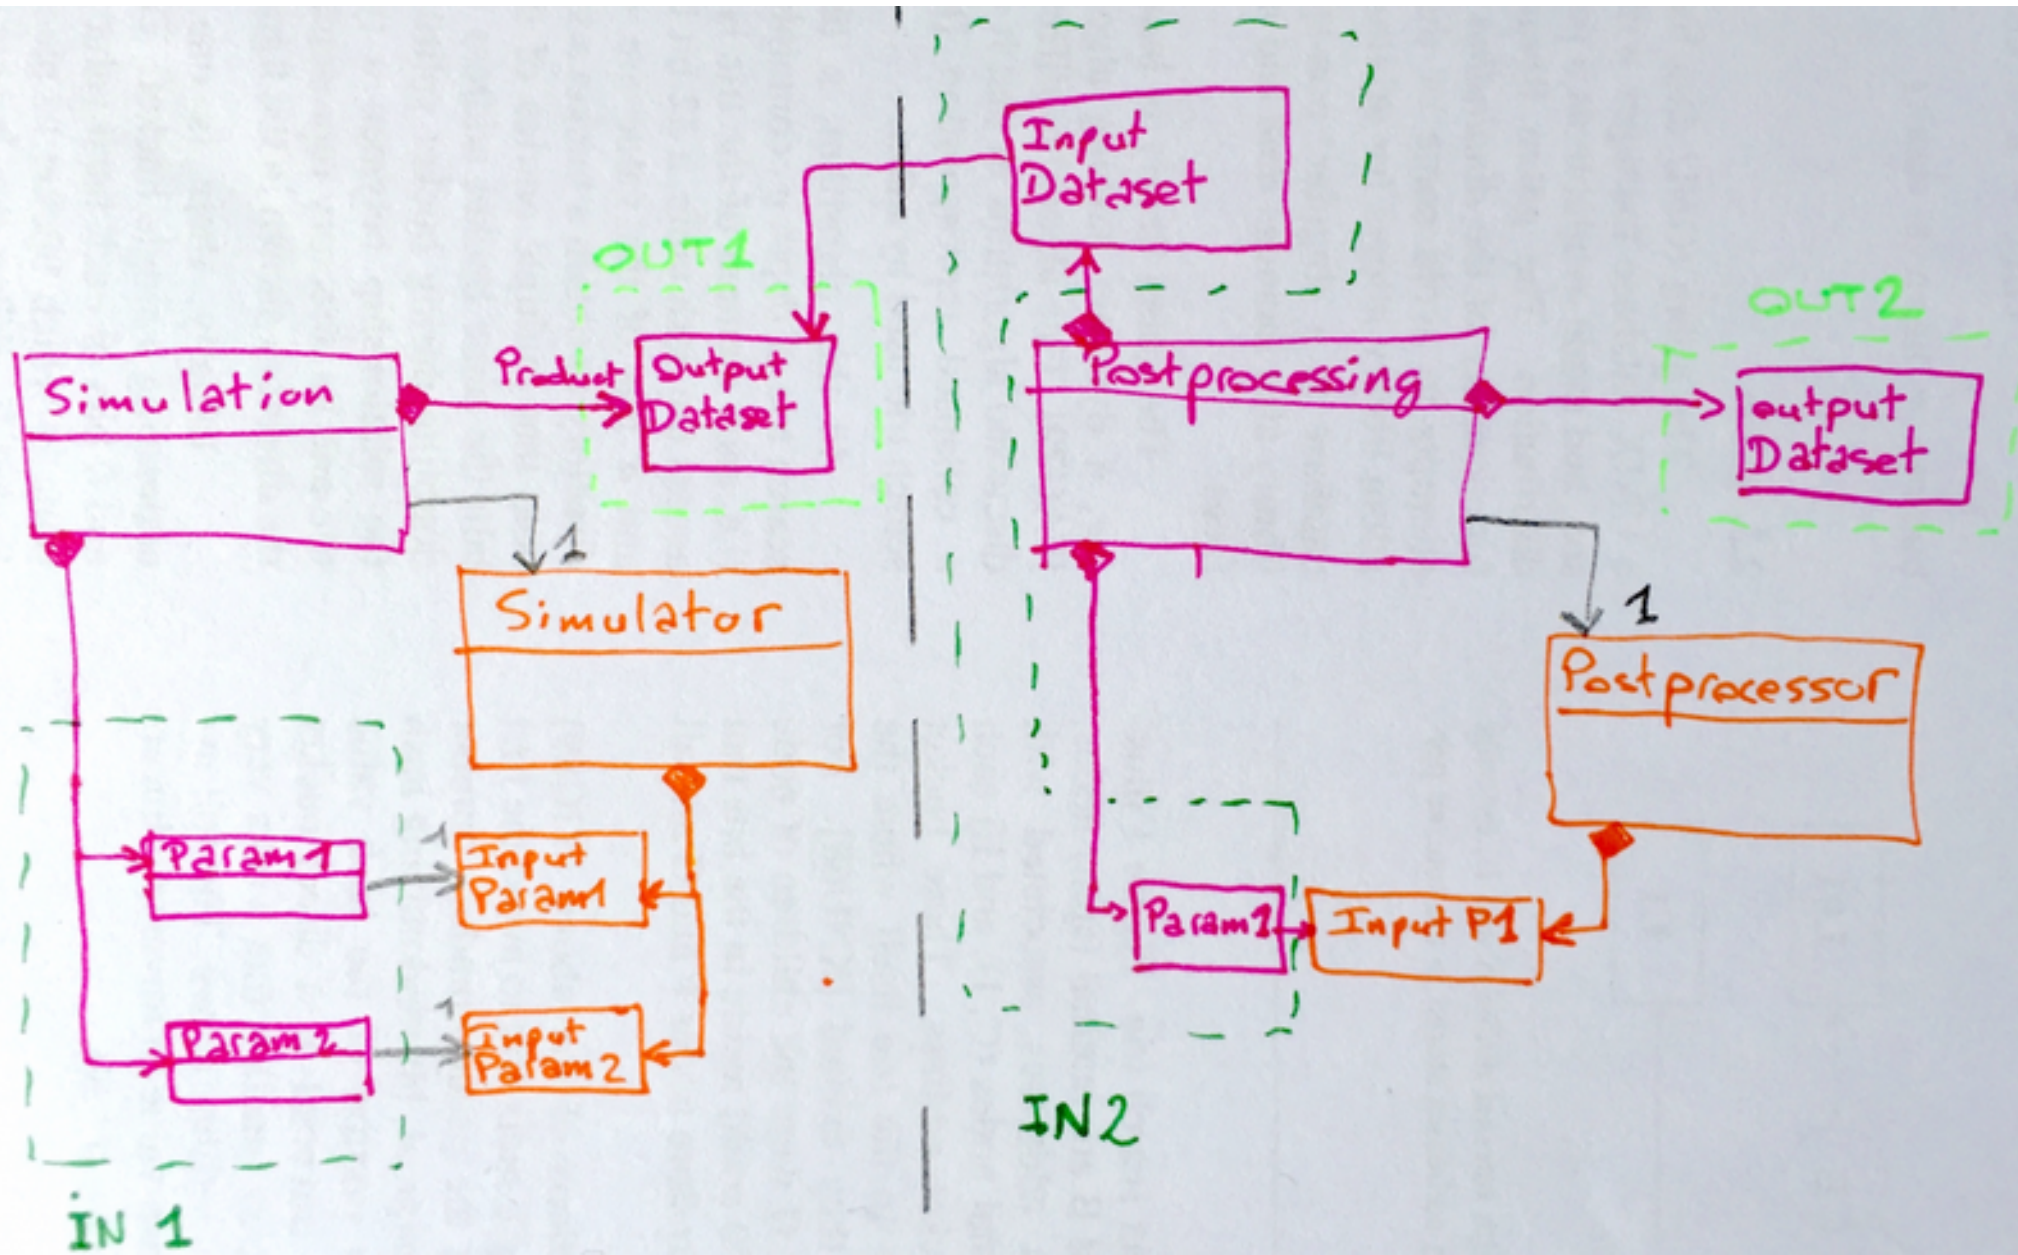

**Strasbourg**

**2016.12.13**

# Basic simulation DM

# Simulations chaining

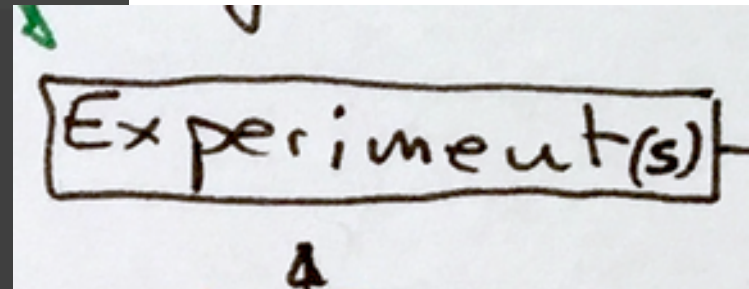

# The whole information is an XML set

- For now, only an XML serialization of SimDM is standard
- A project is a set of XML serializations of the SimDM packages
- The reference between XML files can be either
  - Local to project namespace
  - Global through ivoid
- The API is any XML access method
  - Xpath query
  - Custom relational index from XML files with text search
  - Etc...

# Resource metadata

- Experiment, Protocol and Project are Resources
- A Resource has a set of common metadata

```
<?xml version="1.0" ?>
<ns2:aSimulation xmlns:ns2="http://www.ivoa.net/xml/SimDM/v1.0">
  <identity publisherDID="DM51NoPAH_3_20"/>
  <name>DM51NoPAH_3_20</name>
  <description/>
  <referenceURL/>
  <created>2016-01-20T14:33:17.285163</created>
  <contact>
    <identity publisherDID="n/a"/>
    <role>owner</role>
    <party publisherDID="n/a"/>
  </contact>
```

Experiment(s)

# Experiment metadata

- Basically, an Experiment has metadata about
  - Its input
  - Its produced data (output datasets)

```
<parameter>
  <numericValue>
    <value>2.000000e+01</value>
    <unit>mag</unit>
  </numericValue>
  <inputParameter publisherDID="avmax"/>
</parameter>
```

ID to link Protocol XML file

# Experiment metadata

```
<outputData>
  <identity publisherDID="meshcell1"/>
  <numberOfObjects>871</numberOfObjects>
  <accessURL/>
  <characterisation>
    <statistic>min</statistic>
    <numericValue>
      <value>2.064447e+05</value>
      <unit>cm-3</unit>
    </numericValue>
    <axis publisherDID="protdens"/>
  </characterisation>
  <objectType publisherDID="meshcell"/>
</outputData>
<protocol publisherDID="PDR_1:2_1:28_mathis"/>
```

ID to link Protocol XML file

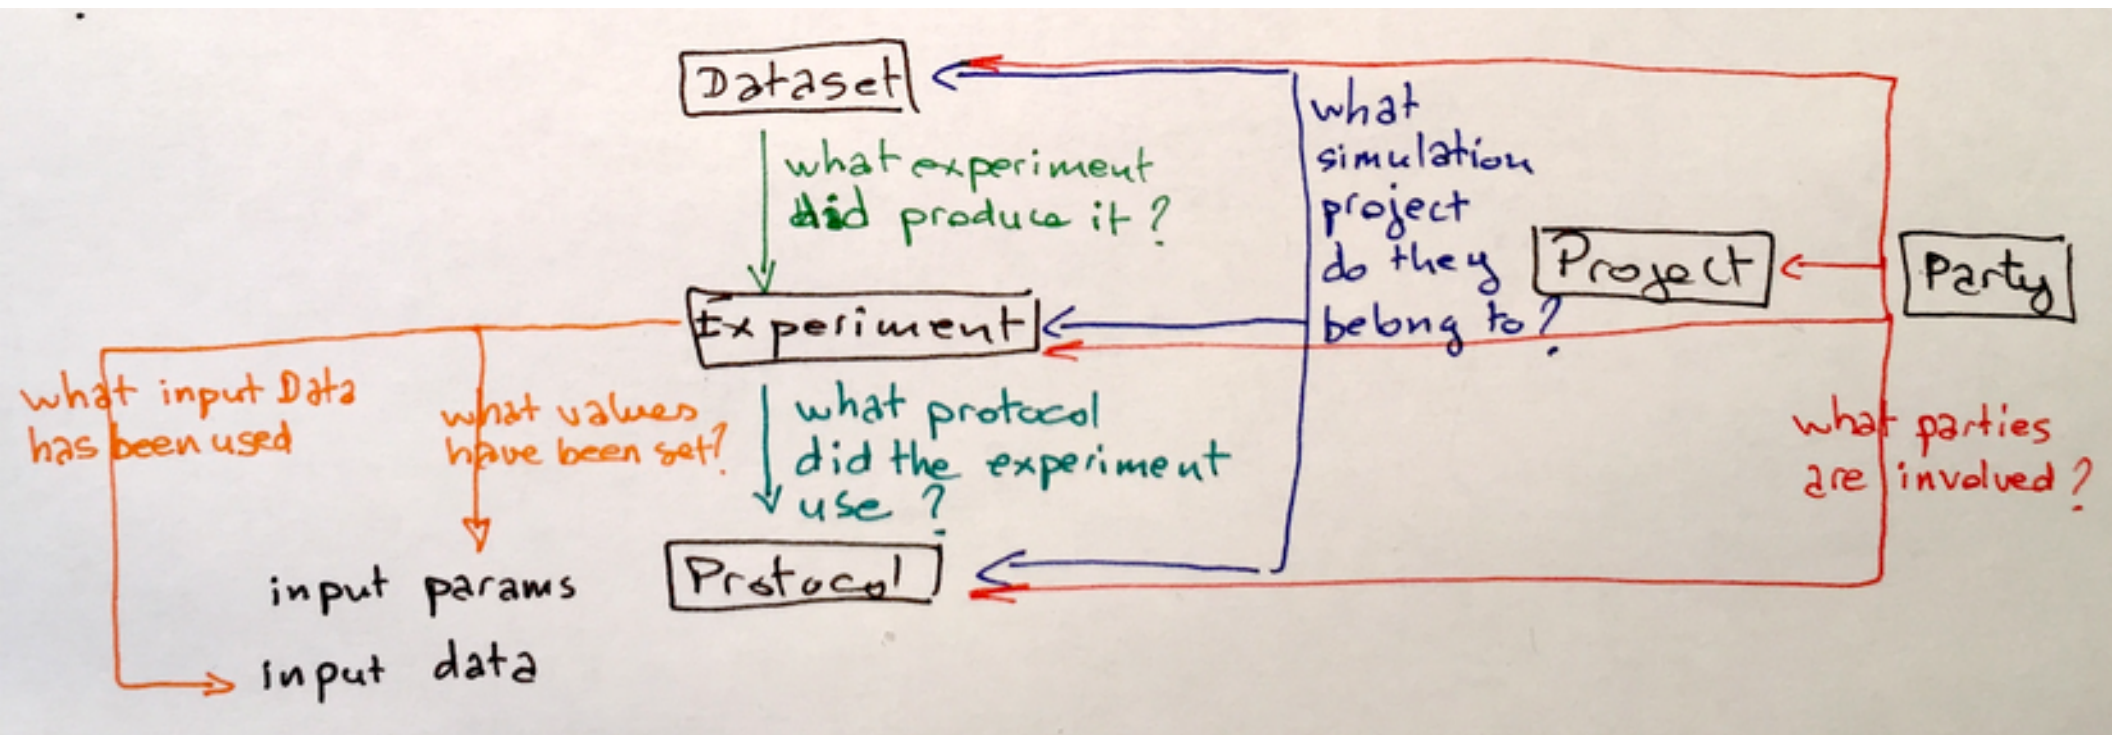

# Experiment metadata (chaining)

```
<?xml version="1.0" ?>
<ns2:aSimulation xmlns:ns2="http://www.ivoa.net/xml/SimDM/v1.0">
  <identity publisherDID="DM51NoPAH_3_20pp"/>
  <name>DM51NoPAH_3_20pp</name>
  <description/>
  <referenceURL/>
  <created>2016-01-20T14:33:17.285163</created>
  <inputData>
    <description></description>
    <url/>
    <product="meshcell1"/>
  </inputData>
  ...
  <protocol publisherDID="PDR_152_postproc"/>
</ns2:aSimulation>
```

ID to link output in another Experiment XML file

# Where does this dataset come from ?

# Take away

- **You can pick only what you want from SimDM**
  - And get very simple data model
- **Basic provenance metadata included in SimDM**
  - Included simulation chaining
- **The only one API to interact with SimDM is XML query**
  - The only one standard serialization is XML
  - Room to develop more user-friendly/use-case-specific UI
  - Not simple to do generic tool because of high abstraction of parts of SimDM. In particular EAV pattern (need attached vocabulary/semantic)
